

Cmpe230 Hw2 Document

In this postfix evaluator homework, first we determined the algorithm of evaluation of input.

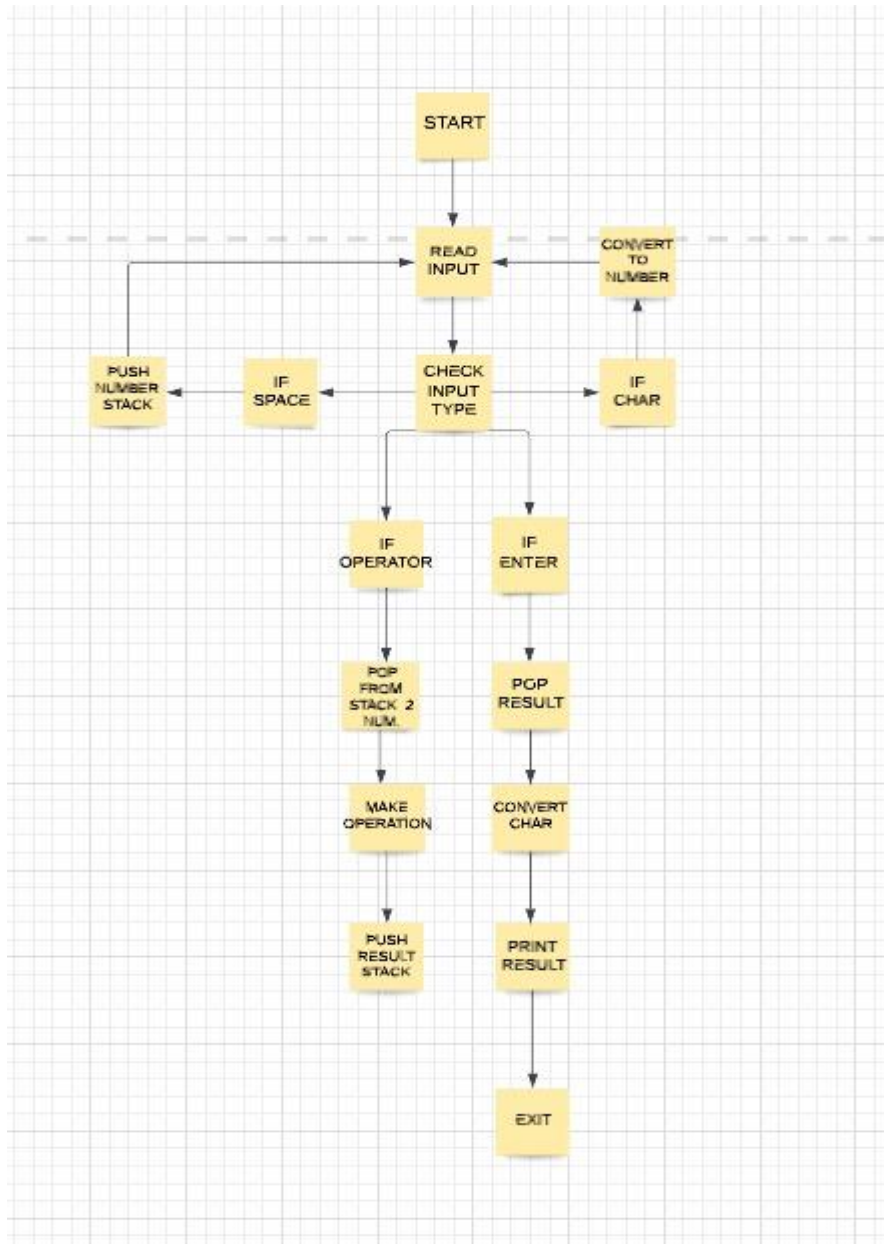

Algorithm Of Postfix Evaluation

Equation: 3 10 5 + *

1. While we are traversing over the input, we may encounter operand or operator.
2. If we see an operand, push it to the stack.
3. If we see an operator, we pop out two operands from stack, since all the operators are binary.
4. At the end, when we completed the input, there will be only one element which is the result of all the expression.

General Work of Our Program

We start by getting expression as input form user character by character. After checking each character, we decide which branch we should move on.

- If character is a number, we get the value of that character and update the value of current value. After that we go back to read character.

- If character is space, we push the current value to the stack and go back to read character.
- If character is operator, we pop out two values and apply the operator to operand. After that, we push the temporary result to the stack.
- If character is enter, we finish the reading input. Pop the final result from the stack, convert it to hexadecimal value then print it as a string. We used ascii table values for this conversion and also others.

ASCII Table

Dec	Hex	Oct	Char	Dec	Hex	Oct	Char	Dec	Hex	Oct	Char	Dec	Hex	Oct	Char
0	0	0		32	20	40	[space]	64	40	100	@	96	60	140	`
1	1	1		33	21	41	!	65	41	101	A	97	61	141	a
